- Understanding and Preprocessing Data
- **Evaluating Machine Learning Algorithms**
- 03 Lab Task

#### PART ONE

# Understanding and Preprocessing Data

## **Machine learning-Outline**

- Raw Data and Feature Representation:
  - ✓ Concepts, instances, attributes
- Pills of Statistics
  - ✓ Sampling, mean, variance, standard deviation, normalization, standardization, etc.
- Data Visualization
  - ✓ how to read a histogram, scatter plot, etc.

- Data is a collection of facts, such as numbers, words, measurements, observations or even just descriptions of things.
- Data can be qualitative or quantitative
  - Qualitative data is descriptive information (it describes something)
  - Quantitative data is numeric information

## **Concepts, Instances, and Attributes**

- Concepts: kinds of things that can be learned
- Instances: the individual, independent examples of a concept
- Attributes: measuring aspects of an instance

| 10 | age | workclass            | education_level | education-<br>num | marital-<br>status     | occupation            | relationship  | race  | sex    | capital-<br>gain | capital-<br>loss | hours-<br>per-week | native-<br>country | income |

## **Loading Data**

```
[1]: # Import libraries necessary for this project
import numpy as np
import pandas as pd
from time import time
from IPython display import display # Allows the use of display() for DataFrames

# Import supplementary visualization code visuals.py
import visuals as vs

# Pretty display for notebooks
%matplotlib inline

# Load the Census dataset
data = pd. read_csv("census.csv")

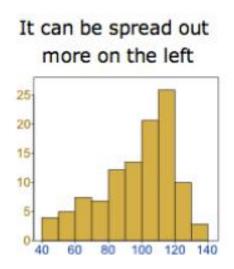

# Success - Display the first record
display(data.head(n=1))
```

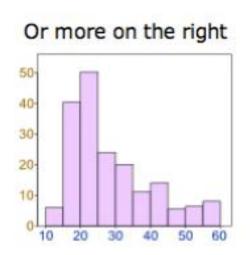

|   | age | workclass | education_level | education-<br>num | marital-<br>status | occupation       | relationship  | race  | sex  | capital-<br>gain | capital-<br>loss | hours-per-<br>week | native-<br>country | income |
|---|-----|-----------|-----------------|-------------------|--------------------|------------------|---------------|-------|------|------------------|------------------|--------------------|--------------------|--------|
| 0 | 39  | State-gov | Bachelors       | 13.0              | Never-<br>married  | Adm-<br>clerical | Not-in-family | White | Male | 2174.0           | 0.0              | 40.0               | United-<br>States  | <=50K  |

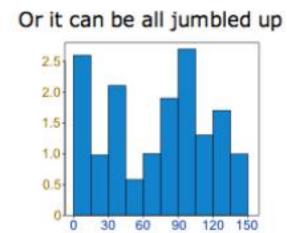

#### Data can be distributed in different ways

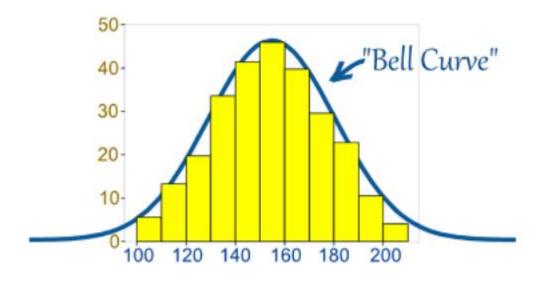

## **Normal Distribution**

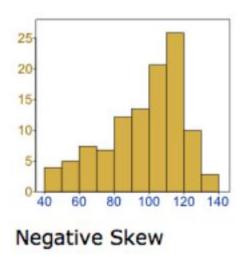

A normal distribution is an arrangement of a data set in which most values cluster in the middle of the range and the rest taper off symmetrically toward either extreme.

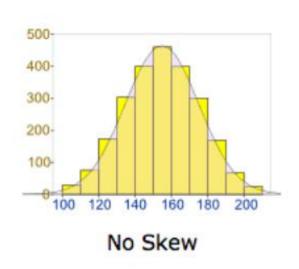

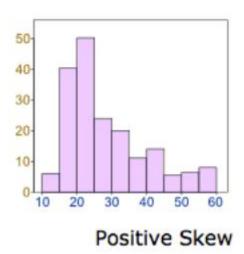

When data is "skewed", it shows long tail on one side or the other:

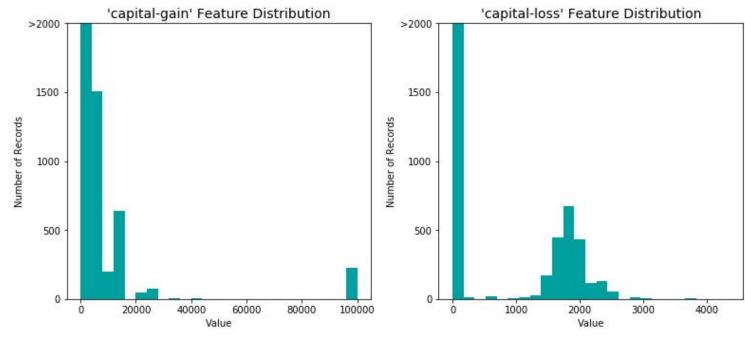

### **Skewed Distributions**

```
# Split the data into features and target label
income_raw = data['income']
features_raw = data.drop('income', axis = 1)
# Visualize skewed continuous features of original data
vs. distribution(data)
```

#### Skewed Distributions of Continuous Census Data Features

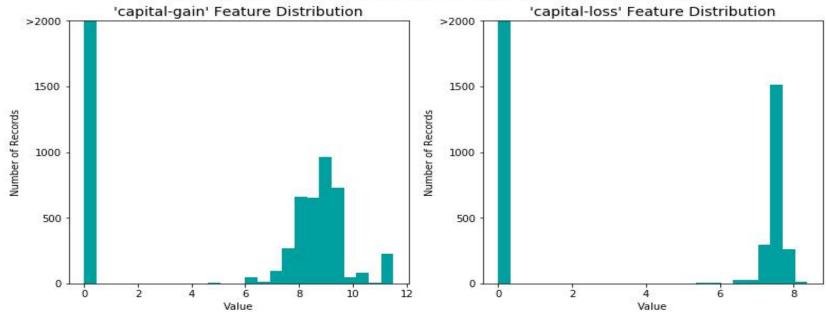

#### **Log-Transformed Distributions**

```
8]: # Log-transform the skewed features
skewed = ['capital-gain', 'capital-loss']
features_log_transformed = pd. DataFrame(data = features_raw)
features_log_transformed[skewed] = features_raw[skewed].apply(lambda x: np.log(x + 1))

# Visualize the new log distributions
vs. distribution(features_log_transformed, transformed = True)
```

#### Log-transformed Distributions of Continuous Census Data Features

## Normalization

To normalize data means to fit the data within unity, so all the data will take on a value between 0 and 1.

$$\mathbf{Ex:} \quad \mathbf{X_{i,\,0\,to\,1}} = \frac{\mathbf{X_i} - \mathbf{X_{Min}}}{\mathbf{X_{Max}} - \mathbf{X_{Min}}}$$

Look at column "age" "education-num"

|   | age      | workclass            | education_level | education-<br>num | marital-<br>status     | occupation            | relationship  | race  | sex    | capital-<br>gain | capital-<br>loss | hours-per-<br>week | native-<br>country |
|---|----------|----------------------|-----------------|-------------------|------------------------|-----------------------|---------------|-------|--------|------------------|------------------|--------------------|--------------------|
| 0 | 0.301370 | State-gov            | Bachelors       | 0.800000          | Never-<br>married      | Adm-clerical          | Not-in-family | White | Male   | 0.667492         | 0.0              | 0.397959           | United-<br>States  |
| 1 | 0.452055 | Self-emp-<br>not-inc | Bachelors       | 0.800000          | Married-civ-<br>spouse | Exec-<br>managerial   | Husband       | White | Male   | 0.000000         | 0.0              | 0.122449           | United-<br>States  |
| 2 | 0.287671 | Private              | HS-grad         | 0.533333          | Divorced               | Handlers-<br>cleaners | Not-in-family | White | Male   | 0.000000         | 0.0              | 0.397959           | United-<br>States  |
| 3 | 0.493151 | Private              | 11th            | 0.400000          | Married-civ-<br>spouse | Handlers-<br>cleaners | Husband       | Black | Male   | 0.000000         | 0.0              | 0.397959           | United-<br>States  |
| 4 | 0.150685 | Private              | Bachelors       | 0.800000          | Married-civ-<br>spouse | Prof-specialty        | Wife          | Black | Female | 0.000000         | 0.0              | 0.397959           | Cuba               |

### **Normalization**

```
# Import sklearn.preprocessing.StandardScaler
from sklearn.preprocessing import MinMaxScaler

# Initialize a scaler, then apply it to the features
scaler = MinMaxScaler() # default=(0, 1)
numerical = ['age', 'education-num', 'capital-gain', 'capital-loss', 'hours-per-week']

features_log_minmax_transform = pd.DataFrame(data = features_log_transformed)
features_log_minmax_transform[numerical] = scaler.fit_transform(features_log_transformed[numerical])

# Show an example of a record with scaling applied
display(features_log_minmax_transform.head(n = 5))
```

|   | age      | workclass            | education_level | education-<br>num | marital-<br>status     | occupation            | relationship  | race  | sex    | capital-<br>gain | capital-<br>loss | hours-per-<br>week | native-<br>country |
|---|----------|----------------------|-----------------|-------------------|------------------------|-----------------------|---------------|-------|--------|------------------|------------------|--------------------|--------------------|
| 0 | 0.301370 | State-gov            | Bachelors       | 0.800000          | Never-<br>married      | Adm-clerical          | Not-in-family | White | Male   | 0.667492         | 0.0              | 0.397959           | United-<br>States  |
| 1 | 0.452055 | Self-emp-<br>not-inc | Bachelors       | 0.800000          | Married-civ-<br>spouse | Exec-<br>managerial   | Husband       | White | Male   | 0.000000         | 0.0              | 0.122449           | United-<br>States  |
| 2 | 0.287671 | Private              | HS-grad         | 0.533333          | Divorced               | Handlers-<br>cleaners | Not-in-family | White | Male   | 0.000000         | 0.0              | 0.397959           | United-<br>States  |
| 3 | 0.493151 | Private              | 11th            | 0.400000          | Married-civ-<br>spouse | Handlers-<br>cleaners | Husband       | Black | Male   | 0.000000         | 0.0              | 0.397959           | United-<br>States  |
| 4 | 0.150685 | Private              | Bachelors       | 0.800000          | Married-civ-<br>spouse | Prof-specialty        | Wife          | Black | Female | 0.000000         | 0.0              | 0.397959           | Cuba               |

## **Feature Representation**

Binary data is a special type of categorical data. Binary data takes only two values.

pandas.get\_dummies(data, prefix=None, prefix\_sep='\_', dummy\_na=False, columns=None, sparse=False, drop\_first=False, dtype=None)[source]
Convert categorical variable into dummy/indicator variables

| 0                       | 1                     | 0                              | 0                                  |     | 0                               | 0                                      | 0                               | 0                            | 0                             | 0                               | 0                                  | 1  | 0                              | 0                                 |
| 0                       | 1                     | 0                              | 0                                  |     | 0                               | 0                                      | 0                               | 0                            | 0                             | 0                               | 0                                  | 0  | 0                              | 0                                 |

### **Feature selection**

#### Feature Selection

✓ Achieves the reduction of the data set by removing irrelevant or redundant features (or dimensions).

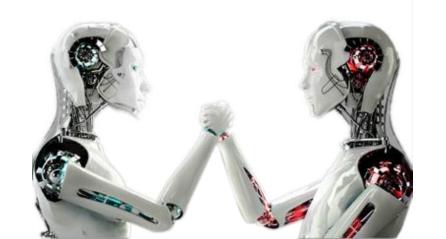

https://scikit-learn.org/stable/modules/classes.html#module-sklearn.feature selection

#### Instance Selection

✓ Consists of choosing a subset of the total available data to achieve the original purpose of the DM application as if the whole data had been used.

#### PART TWO

# Evaluating Machine Learning Algorithms

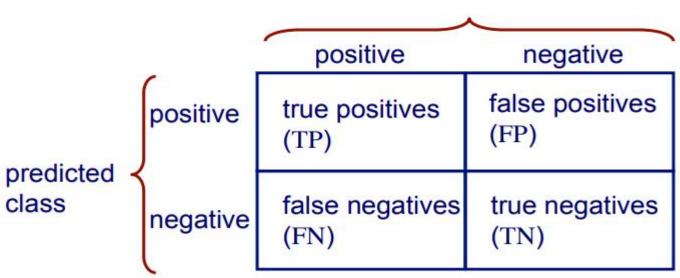

- > Is accuracy an adequate measure of predictive performance?
- accuracy may not be useful measure in cases where there is a large class skew
  - ✓ Is 98% accuracy good if 97% of the instances are negative?
- ➤ there are differential misclassification costs say,getting a positive wrong costs more than getting a negative wrong
  - ✓ Consider a medical domain in which a false positive results in an extraneous test but a false negative results in a failure to treat a disease
- > we are most interested in a subset of high-confidence predictions

## **Evaluation-accuracy metrics**

#### actual class

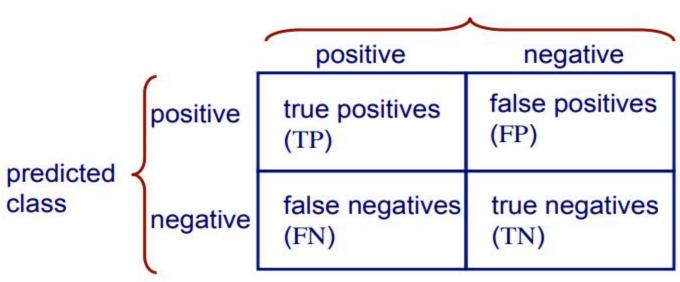

recall (TP rate) = 
$$\frac{TP}{\text{actual pos}}$$
 =  $\frac{TP}{TP + FN}$   
precision =  $\frac{TP}{\text{predicted pos}}$  =  $\frac{TP}{TP + FP}$ 

## Evaluation-accuracy metrics

#### actual class

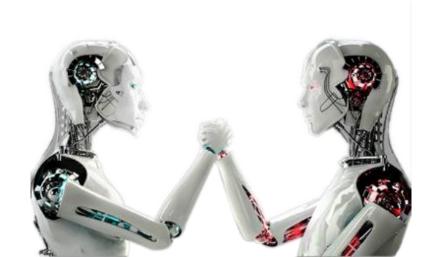

recall (TP rate) = 
$$\frac{TP}{\text{actual pos}}$$
 =  $\frac{TP}{TP + FN}$   
precision =  $\frac{TP}{\text{predicted pos}}$  =  $\frac{TP}{TP + FP}$ 

$$F_{\beta} = (1 + \beta^{2}) \bullet \frac{precision \bullet recall}{(\beta^{2} \bullet precsion) + recall}$$

#### PART THREE

## Lab Task

- 1. Complete the exercises and questions in the lab02\_preliminary.pdf
- 2. Submit your result file with an extension ".ipynb" to BB.

## Thanks

贾艳红 Jana Email:jiayh@mail.sustech.edu.cn
